BrandCheck

Source-linked content review with a human decision at the end.

ONE-MINUTE JUDGE PATH

Open the demo, review the prepared NovaDesk post, inspect the four findings, revise the text and alt text, submit a version, then switch to Reviewer - demo to approve it.

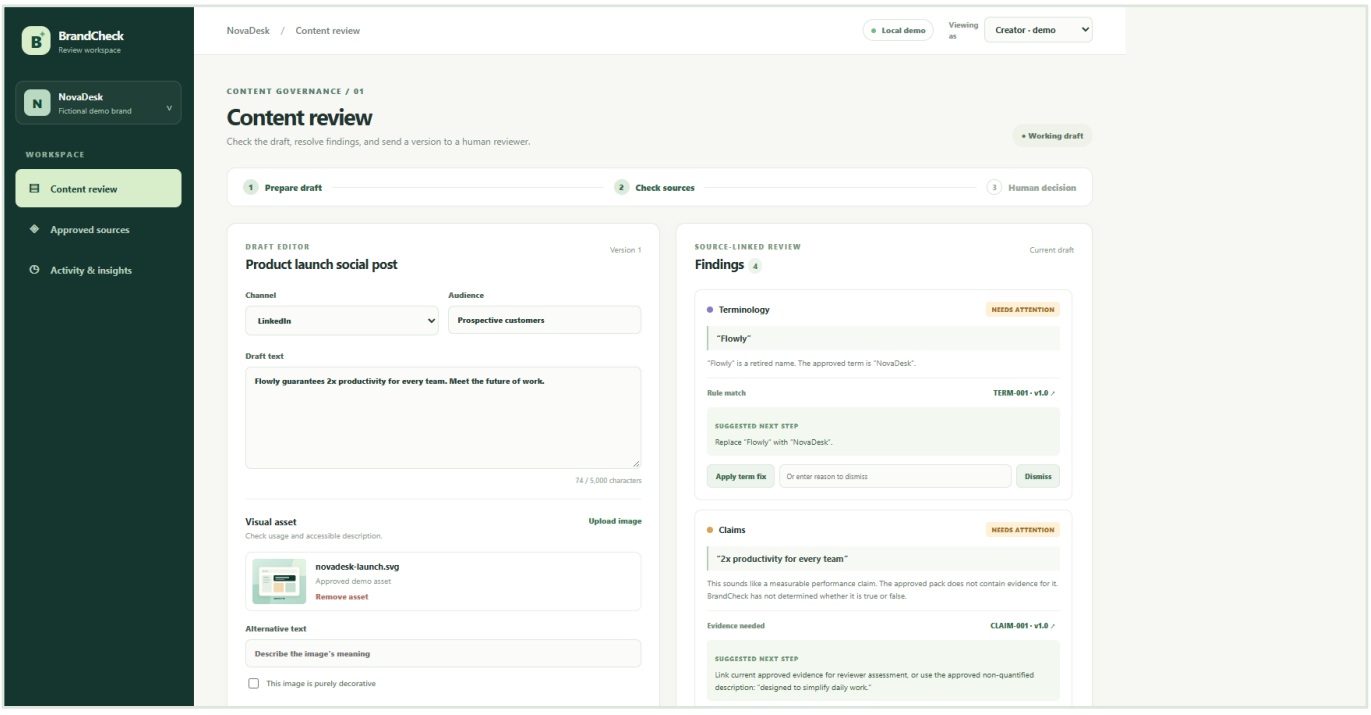

WORKING PRODUCT

https://manas-jain-24.github.io/brandcheck/

PUBLIC SOURCE REPOSITORY

https://github.com/Manas-Jain-24/brandcheck

THE PRODUCT IN USE

Fictional brand and content. No sign-in or API key is required to use the public demo.

01 / PROBLEM AND SOLUTION

A review before publication

Growing teams publish through employees, agencies and tools. Retired names, unsupported promotional claims and inaccessible visuals can reach audiences before a brand manager notices. BrandCheck focuses on the pre-publication decision: a creator sees specific issues and a reviewer retains the final say.

WHO USES IT

- Creators: writers and marketers need fast, understandable corrections that preserve their intent.
- Brand managers: need approved sources, traceable decisions and visibility into repeated mistakes.
- Authorised reviewers: need to see what changed and why a finding was dismissed before approval.

COMPLETE WORKING WORKFLOW

01 Open a prepared draft
The public demo starts with a fictional NovaDesk social post and approved sample image.

02 Run source-linked checks
The app flags the retired name, a claim needing evidence, absolute wording and missing alt text.

03 Revise with control
The creator edits text or applies the name fix, adds alt text, and may dismiss a finding with a reason.

04 Request human approval
Submitting stores a version. The demo reviewer compares it with the original, comments and decides.

05 Inspect history
Decisions, versions and issue categories remain visible across reloads in the same browser tab.

COMPLETED FEATURES

Versioned source pack and custom terms; text and image intake; terminology, claim, tone, alt-text and asset checks; evidence expiry; source-cited findings; creator dismissals; reviewer comments and decisions; revision comparison; local issue insights.

02 / TECHNICAL PLAN AND PROOF

Built for a usable public demo

The team had GitHub access but no external database or backend server. A static app gives judges a public, self-serve journey without credentials, while the checks remain explicit about what they can and cannot establish.

ARCHITECTURE

React + TypeScript (Vite) - creator, reviewer and source screens

Versioned brand pack - approved rules, terminology and demo evidence

Review engine - exact matches plus disclosed claim/tone heuristics

sessionStorage - synthetic draft, versions, comments and decisions

GitHub Actions + Pages - repeatable public build and deployment

MOST DIFFICULT PART: RELIABLE, EXPLAINABLE FINDINGS

A finding carries a source ID and version, an excerpt, location, severity, evidence status, explanation and suggested next step. The engine cites only active sources. A numerical claim without current evidence is marked Evidence needed, not false. Reviewer-entered evidence has an expiry and is not independently verified by the app.

VERIFICATION COMPLETED

- Five review-engine tests pass: sample issues, clean content, retired source, uploaded asset and evidence expiry.
- Browser walkthrough passes: sample review, revision, zero-finding recheck, reviewer approval and reload persistence.
- Live GitHub Pages deployment succeeded; public route opens without sign-in and returns source-linked findings.
- Mobile-width browser check found and fixed a horizontal overflow issue. No page runtime errors appeared in the walkthrough.

RESPONSIBLE DESIGN

Only fictional demo data is used. Content stays in the current browser tab; no server, analytics SDK or external service receives it. Demo role switching is clearly labelled, and real confidential work requires authenticated storage and server-side access checks.

What changed from Round 1

The Round 1 plan named Next.js and Supabase. The delivered Round 2 demo uses React/Vite, GitHub Pages, sessionStorage and transparent rule-based checks because the team had only GitHub access. It does not claim a complex backend, real multi-user collaboration or production security.

THREE SUBSTANTIAL ROUND 3 IMPROVEMENTS

1 Grounded semantic review
Add nuanced tone and claim analysis with retrieved approved evidence, citations and uncertainty; retain human control.

2 Real shared review
Add authenticated workspaces, server-side roles and an audit trail across separate creator and reviewer accounts.

3 Document intake
Extract PDF/DOCX content and return findings with page or paragraph locations.

LIMITS AND CONTRIBUTION RECORD

- Heuristics can miss paraphrases, visual misuse or inaccurate alt text. Image identity is a fingerprint check, not visual recognition. Demo data is not shared across devices.
- Manas Jain: product direction, sample journey, UI design, implementation and acceptance testing.
- Mayank kumar: teammate with a planned data and review QA role. His completed contribution statement should reflect his actual work.

BUILD RECORD AND VERIFICATION

First product commit: 26 October 2026, 1:49 AM IST. Code, UI, tests and documentation were built for this project. No Inkloom source code or earlier product template was copied.
